The Role of Chemically Defended Seaweeds as Biodiversity Sources

Renato Crespo Pereira,* Bernardo Antonio Perez da Gama and Daniela Bueno Sudatti

Introduction

Seaweeds are ecologically important components of coastal areas as primary producers, competitors, and ecosystem engineers that play a central role in coastal habitats such as rhodolith beds, kelp forests and coral reefs. These organisms have been recognized for long time as fundamentally important worldwide to benthic marine environments, in polar (Wienecke and Amsler 2012), temperate (Huovinen and Gómez 2012) and tropical (Mejia et al. 2012) regions.

As primary producers, seaweeds are the basis of most marine food webs (with the exception of chemosynthetic, deep sea ecosystems), and provide direct sources of nutrients and energy for consumers, such as food for herbivores (Aquilino and Stachowicz 2012), dissolved particles for filter feeders (Wilson 2002) and available substrata for bacteria (Paradas et al. 2010) and macrobenthic colonization (da Gama et al. 2008a). Besides these basic ecological roles, many seaweeds provide shelter and habitat for a rich and varied fauna of small invertebrates (Christie et al. 2009) and epibiotic communities (Egan et al. 2013), promote sediment stabilization (Madsen et al. 2001) and supply atmospheric oxygen.
